ACKNOWLEDGEMENTS

This is optional and should be at most half a page. Thanks Ma, Thanks Pa. One paragraph in normal language is the most respectful.

Do not use too much bold, any figures, or sign at the bottom.

DEDICATION

This is optional.

Abstract

A short, abstracted description of your essay goes here. It should be about 100 words long. But write it last.

An abstract is not a summary of your essay: it's an abstraction of that. It tells the readers why they should be interested in your essay but summarises all they need to know if they read no further.

The writing style used in an abstract is like the style used in the rest of your essay: concise, clear and direct. In the rest of the essay, however, you will introduce and use technical terms. In the abstract you should avoid them in order to make the result comprehensible to all.

You may like to repeat the abstract in your mother tongue.

Contents

1. Introduction

Particle Physics or sometimes called High Energy Physics: is the field of physics that pursues the ultimate structure of matter, this possible in two ways, one is to look for elementary particles, the ultimate constituents of matter at their smallest scale and the other is to clarify what interactions are acting among them $(forces)$ to construct matter as we see it.

There are four forces in nature, gravity, electromagnetism, weak nuclear force and strong nuclear force. In this essay our work will be on the strong nuclear force.

1.1 Strong Force

The gauge bosons that mediate this interactions are eight gauge bosons called gluons, which come from the gauge group $SU(3)$ which has eight generators, gluons mediate the interaction between quarks.

Gluon is massless spin 1 particle, carrying charge called colour charges, glouns look like photons but photons do not carry electric charge, because of this glouns can interact among themselves unlike photons. Normally the range of the force can be calculated by a simple argument of the uncertainty, but this not the case for the strong force, the strong force is more complicated and involves a concept known as confinement.

The colour charge has strange property that it exerts a constant force that binds colour carrying particles together, this can be visualized using the analogy of a rubber band, the stronger you pull on the rubber band the tighter it feels. If you do not pull on it at all, it hang loose. The same thing happens for the particles, that means at a very short distance, the force is relaxed and the particles behave as a free particles, as the distance between them increases the force act like a rubber band, the force get them back in stronger pulling and when the rubber band is stretched beyond its limits then it will cut into many pieces producing more hadrons. This phenomenon is known as the colour confinement. In other words those particle tend not be separated by a macroscopic distance. This limits the range of strong force, which is believed to be on order of $10^{-15}m$, the dimension of a nuclear particle.

The theory which describes this force is called $Quantum\ Chromodynamics.$

1.2 Quarks

Quarks and leptons are the building blocks which build up matter. In the present there are six "flavours" of quarks, these are up, down charm strange, top and bottom, and can written as

$$\begin{pmatrix} up \\ down \end{pmatrix} ; \qquad \begin{pmatrix} charm \\ strange \end{pmatrix} ; \qquad \begin{pmatrix} top \\ bottom \end{pmatrix}$$

1

Name (flavour)	symbol	charge(in units of e)	mass
Up	U	$+\frac{3}{2}$	$1.7-3.1\frac{Mev}{c^2}$
Down	d	$-\frac{1}{3}$	$4.1-5.7\frac{Mev}{c^2}$
charm	d	$+\frac{1}{3}$	$1.18-1.34\frac{Gev}{c^2}$
strange	d	$-\frac{1}{3}$	$80-130\frac{Mev}{c^2}$
top	d	$+\frac{1}{3}$	$172.3-173.5\frac{Gev}{c^2}$
bottom	d	$-\frac{1}{3}$	$4.13-4.37\frac{Gev}{c^2}$

Table 1.1: properties of Quarks

Quarks can successfully a count for all known mesons and baryon, where mesons are consist of quark and anti quark and baryons are consist of three quarks or three anti quarks.

Quarks carry colour quantum number: red, green or blue, since all hadrons are colour charge neutral, they must have white charge.

Unlike other elementary particles quarks carry fractional charge and posses new quantum number. The next table summarize some properties of quarks. Each quark flavour is associated with an own quantum number, which is conserved in strong and electromagnetic interactions but not in weak interaction. These are:

-Strangeness: $S = -1$ for s-quark.

-Charm: $C = +1$ for c-quark.

-Beauty: $\tilde{B} = -1$ for b-quark -t-quark has life time too short to form hadrons

-up and down quarks have nameless flavor quantum numbers.(Nagashima and Nambu, 2010)

1.3   Large Hadron Collider

Hadron colliders are devices made to explore the world of particle physics, they work as theories testers and also as a discovery machines, an example of these hadron colliders is the LHC in CERN. In the Large hadron collider two beams of hadrons(protons) are being accelerated to a high kinetic energy and then collided with each other. It has started operation in 2009 and in 2013 the Higgs particle has been discovered in LHC. Most of the interesting physics at LHC involves investigating the results of these interactions(collisions), as a result of this collision stable partons are formed, partons consists of quarks and qluons. Because of the complex nature of the event at the hadrons colliders, the description of the final state involves a multi-particle calculations. The accurate prediction of the final state in hadron colliders is still one the hardest problems, this problem roots to the non-abelian nature of QCD, which leads to a colour confinement at a long distances. The two main problems are the description of the hadron formation and the evolution of QCD final states from short to long distances. Those problems can be tackled to a good approximation by Monte-Carlo event generators.

1.4   The Parton Shower

In general parton showers are approximations of the higher order real emission corrections to the hard scattering. The word hard here means, the process involves a transfer of large momentum, either a violent scatter or creation of large mass. They locally conserve flavour and four momentum, and also they are consistent, which means, the particle either splits into two or not. Since the parton showers are simulate of the branching and splitting processes, the quality of their predictions depend on precise is the implementation, for example one can ensure the colour coherence through selecting an evolution variable representing the angular ordering, although, this in not the only choice to ensure the colour coherence (Höche, 2014). In the following we will at a simple implementation of a parton shower in python.

1.5   Hadronization

To reflect the colour neutrality of the particles in our model the partons will be transformed into a stable hadrons which are colour neutral, this process is called hadronization. The first implemented model and also follows Monte-Carlo event generators was Feynman-Field Model, which gives an idea of the formation of the mesons through iteratively from a single quark. However, this model is not collinear safe, which means the model can mix the short and long distance physics. Now a days two models are common, the string model and clustering model(Höche, 2014).

1.6   Monte Carlo Method

Monte Carlo method is set of mathematical tools that first used by scientist to generate game chance that its behaviour can be used to study interesting phenomena. In our context the definition of Monte Carlo method would be, that in which the usage of random numbers is deliberate in a calculation that involves a sequence of states whose evolution can be considered random(Höche, 2014).

1.6.1 Pseudo-random numbers. In a computer these are generated using a deterministic algorithm that generates a set of numbers that exhibits statistical randomness, those numbers are called pseudo-random.[the book]

The main properties of a good random generator are:

- **Long period**: the pseudo-random generators have a finite range after which they begin to repeat themselves, for a good random generator this range should much longer than the amount of numbers that are needed for the calculation.

- **Randomness**: The numbers should follow the uniform distribution and also should be independent of each other.

(a) pi value   (b) The uncertainty

Figure 1.1

- **Repeatability**: The same initial values should give the same sequence of a random numbers, this important for testing because one might need to repeat the calculation or in the coding terms debugging.

- **Portability**: One should be able to generate the same sequence in different machines.

- **Fast**: the generation of the pseudo-random numbers should not be time consuming(Weinzierl, 2000).

1.6.2 Samples with different PDFs. Generating samples of different probability distribution function(pdf) is essential since we are simulating various variables that have different numerical behaviour. For example if our pseudo-random numbers are uniformly distributed in the interval [0,1] and a sequence of specified distribution is needed. I will mention two methods, which are used in this essay.

1.6.3 The acceptance-rejection method. The acceptance-rejection method was developed by von Neumann. Assume we have a sample x which is uniformly distributed and the pdf is denoted by f(x), and the unknown pdf is denoted by p(x), we assume that we can enclose p(x) inside a shape that is f(x).

In simple words, one first generates x according to the uniform distribution and then calculates p(x) and f(x), then generates another number which is also uniformly distributed, and checks $y \times f(x) \leq p(x)$. If this the case then accept x, if not reject x and start again. Example of this method is calculation of pi, assume we have a box of side length D and a circle of diameter D inside that box, now the probability that a point in the box and is also in the circle is approximately the area of the circle over the area of the box, which is π over 4 here, hence, from this we can approximate the value of π. The histograms in Figure 1 exhibits this calculation and also the error in the calculation(Weinzierl, 2000).

(a) Theta values   (b) The uncertainty
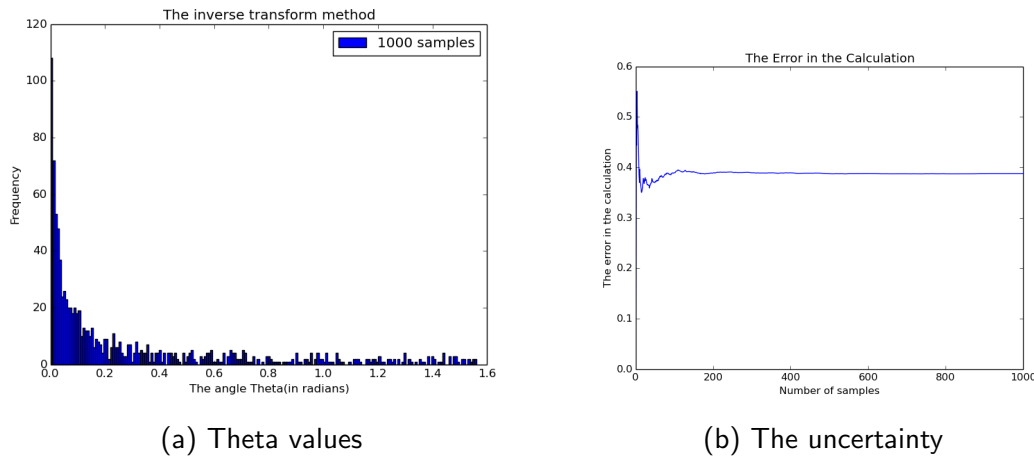

Figure 1.2

1.6.4 The inverse transform method. Let x be a random with pdf $p(x)$ that takes values in the interval [0,1] and let y be a random variable that is uniformly distributed in the interval [0,1]. We set

$$x = p^-1(y) \qquad (1.6.1)$$

One application of this method is the importance sampling, in which certain values are pre-ferred(Weinzierl, 2000). Example of this is generating an angle theta in the interval $[0, \pi/2]$ that is inversely distributed, where the small angles are desired. The histograms in figure 2 demonstrate this and the error in the calculation.

1.6.5 The module random in python. The samples above were generated using $python$ module random, here are few words about this module.

This module implements pseudo-random number generators for various distributions.

For integers, there is uniform selection from a range. For sequences, there is uniform selection of a random element, a function to generate a random permutation of a list in-place, and a function for random sampling without replacement.

On the real line, there are functions to compute uniform, normal (Gaussian), lognormal, negative exponential, gamma, and beta distributions. For generating distributions of angles, the von Mises distribution is available.

Almost all module functions depend on the basic function random(), which generates a random float uniformly in the semi-open range $[0.0, 1.0)$. Python uses the Mersenne Twister as the core generator. It produces 53-bit precision floats and has a period of $2 ** 19937 - 1$. The underlying implementation in C is both fast and threadsafe. The Mersenne Twister is one of the most extensively tested random number generators in existence.

182 1.7   Parton Shower Simulation

183 The following is a simple simulation in python for a splitting of a single quark, the simulation
184 accounts for the four momentum conservation of the soft particles.

185 **1.7.1 Physical description.** As a result of a hadrons collision, quarks will fly away. Since they
186 are charged particles(colour charge), the moving quarks will radiate. The quark will lose part of
187 its energy emitting a gluon. If at the beginning, the quark had energy E_i and radiates energy
188 E_{rad}, then the qluon takes $\frac{E_{rad}}{E_i}$ of the particle's initial energy. It is radiated at an angle of θ
189 to the quark initial direction. The quark will fly on radiating another gluon and so on until it
190 becomes stable(the hadronization starts). The radiated gluons will decay into two quarks, which
191 will later radiates gluons, which will radiate gluons again and so on. The result is a shower of
partons decaying into two partons.

192
193 Now we begin with 4- momentum vector

$$P^\mu = \begin{pmatrix} E/c \\ p_x \\ p_y \\ p_z \end{pmatrix} \; ; P_\mu = \begin{pmatrix} E/c \\ -p_x \\ -p_y \\ -p_z \end{pmatrix} \tag{1.7.1}$$

194 And the inner product is given by

$$P^\mu P_\mu = P^\mu \eta_{\mu\nu} P_\nu = (m_0 c)^2 \tag{1.7.2}$$

195

$$P^\mu P_\mu = \left(\frac{E}{c}\right)^2 - (p_x^2 + p_y^2 + p_z^2) = (m_0 c)^2 \tag{1.7.3}$$

196 Now considering the natural units $c = 1$ this can be written as

$$m_0^2 = E^2 - \|p\| \tag{1.7.4}$$

197 Which is lorentz invariant quantity i.e does not depend on the frame. In our case the quarks in
198 (LHC), the mass of the quark ~ 1 Mev and the energy of the hadrons is ~ 1 Tev, hence, we can
199 assume that the mass of the quark(1.7.4) is 0.

200   From the conservation of energy and momentum,

$$P_i^\mu = P_f^\mu. \tag{1.7.5}$$

201   We assume that the intial patricle is moving in x -direction, we can write the initial 4-momentum
202   as $P_i^\mu = (E, E, 0, 0)$, afterwards the particle will split. Therefore, the final momentum is given
203   by $P_{rad} + P_{part}$, part here refers to the particle which has lost part of its energy, so $P_{rad} =$
204   $(E_{rad},\ cos\theta \cdot E_{rad},\ sin\theta \cdot E_{rad},\ 0)$. From this, and since the particle is rotated with θ we can
205   find the direction of the particle(part) with help of the rotation matrix

$$R = \begin{pmatrix} \cos\theta & -sin\theta \\ \sin\theta & \cos\theta \end{pmatrix} \tag{1.7.6}$$

206   The direction of the particle of the fraction enregy can be found using the following equation

$$P_{part} = P_i - P_{rad}. \tag{1.7.7}$$

207   In a three dimensional world, we have two rotation angles, the angular angle and the azimuthal
208   angle. Given a unit vector $u = (u_x, u_y, u_z)$, where $u_x^2 + u_y^2 + u_z^2 = 1$,the matrix for rotating this
209   particle by angle θ about an axis in the direction of u is

$$\begin{pmatrix} \cos\theta + u_x^2(1-\cos\theta) & u_x u_y(1-\cos\theta) - u_z\sin\theta & u_x u_z(1-\cos\theta) + u_y\sin\theta \\ u_y u_x(1-\cos\theta) + u_z\sin\theta & \cos\theta + u_y^2(1-\cos\theta) & u_y u_z(1-\cos\theta) - u_x\sin\theta \\ u_z u_x(1-\cos\theta) - u_y\sin\theta & u_z u_y(1-cos\theta) + u_x\sin\theta & \cos\theta + u_z^2(1-\cos\theta) \end{pmatrix} \tag{1.7.8}$$

210   **1.7.2 Implementation in python.** First we will start with case of 2 dimensions model which
211   accounts for one rotation matrix θ and it evolves generation of two random numbers, one them
212   represent the angle and the other regards the energy of the radiated particle. Here both the
213   energy fraction z and the angle $\theta$are following the distribution $1/x$, where the former lies in the
214   interval $[0.25, .75]$ and the later in the interval $[0,\pi/2]$ and they are generated by applying the
215   inverse transform method on a set of numbers that are uniformly distributed.

216   As for the four momentum vector, the module $numpy$ is used for this purpose, here we use the
217   object $array$. Numpy is a scientific computing package in python which is widely used for these
218   purposes, beside that it has powerful N-dimensional arrays it also has useful linear algebra tools
219   and random number capabilities.

220   following the physical description a list contains the four momentum of the initial particle was
221   defined, then we assumed that the particle has initial energy $= 1$ energy unit, since the particle
222   will split after certain distance an assumption of the distance before the decay was made is that
223   the particle will move a distance of 1 unit and then it will decay, basically it is an iteration process,
224   at the beginning we check the energy of the particle if it is a above the stability limit, which
225   we assumed to 0.09, this particle will split, the direction of the radiated will follow the θ and its
226   energy will be given from z, and then both new particles four momenta will be add to the list
227   at the beginning and again those particles will be checked, now if the particle has energy that is
228   equal or below the stability limit then the iteration process will be terminated.

229 As for plotting the results, the library $matplotlib$ was used which is a library that is used to
230 make 2 D plots in Python, as $matplotlib$ has the ability to add many lines at once, here the
231 Linecollection is used, which is a package in $matplotlib$, the diagram in figure 3 shows the 2 D
232 simulation of the parton shower.
Figure 1.3: 2D simulation of the spliting of a single parton, here the colour fades as the energy decreases

233 The 3D simulation of the parton shower is essentially the same as for python code with few
234 changes, in which now we have two rotation angles, θ and also ϕ which is the azimuthal angle
235 which is uniformly distributed in the interval $[0,2\pi]$. To simulate the rotation in three dimensions,
236 the function $normv(u)$and function !rotation(v,angle)!,the former returns the axis of the
237 rotation, the function input and the vector $[1,1,1]$ from a plane, from which we find a vector that
238 is orthogonal to this plane, and the later is matrix of rotation, it takes the angle rotation and the
239 axis of rotation as inputs.

240 Also here z (the energy fraction) now is lies the interval[0,1] and the stability limit is 0.05. The
241 digram in figure 4 shows the 3D simulation of single parton splitting.

Figure 1.4: 3D simulation of the spliting of a single parton

2. The Second Chapter

Text text text text text text text text text text text text text text text text text text text text text text text text text text.

When you get stuck, don't panic. The world is unlikely to end just now. Remember you can consult your supervisor, tutor, and Blaise at agreed times.

2.0.1 Theorem (Jeff's Washing Theorem). *If an item of clothing is too big, then washing it makes it bigger; but if it is too small, washing it makes it smaller.*

Proof. Stated without proof. But a proof would look like this. □

Notice that no Lemmas are required in the proof of Theorem 2.0.1.

3. Third Chapter

Theorems before the chapter's first section will be dot-zero, and their numbering is completely wrong. You can avoid this by simply always starting a chapter with a section. Ta Da! It will probably help you structure your essay anyway.

3.0.1 Theorem (My Theorem2). *This is my theorem2.*

Proof. And it has no proof2. □

3.1 See?

$$x = y + y \tag{3.1.1}$$
$$= 2y \tag{3.1.2}$$

see equations (3.1.1) and 3.1.2

3.2 More

Here's a conjecture

3.2.1 Conjecture. The washing operation has fixed points.

and here's an example

3.2.2 Example. 100 FRW coin.

3.2.3 This is a subsection.

273 ## 3.3   This is a section

4. The Second Squared Chapter

An average essay may contain five chapters, but I didn't plan my work properly and then ran out of time. I spent too much time positioning my figures and worrying about my preferred typographic style, rather than just using what was provided. I wasted days bolding section headings and using double slash line endings, and had to remove them all again. I spent sleepless nights configuring manually numbered lists to use the LaTeX environments because I didn't use them from the start or understand how to search and replace easily with texmaker.

Everyone has to take some shortcuts at some point to meet deadlines. Time did not allow to test model B as well. So I'll skip right ahead and put that under my Future Work section.

4.1 This is a section

Text text text text text text text text text text text text text text text text text text text text text text text text text text text text text text text text text text text text text text text text text text text text text text text text text text text.

Some essays may have 3, 5 or 6 chapters. This is just an example. More importantly, do you have at most 35 pages? Luck has nothing to do with it. Use the techniques suggested for writing your essay.

Now you're demonstrating pure talent and newly acquired skills. Perhaps some persistence. Definitely some inspiration. What was that about perspiration? Some team work helps, so every now and then why not browse your friends' essays and provide some constructive feedback?

5. Testing
